Applicant

ADVANCED COMMUNICATIONS CONSULTANCYet al.

1. The applicant is hereby notified that this International Preliminary Examining Authority transmits herewith the international preliminary examination report and its annexes, if any, established on the international application.
2. A copy of the report and its annexes, if any, is being transmitted to the International Bureau for communication to all the elected Offices.
3. Where required by any of the elected Offices, the International Bureau will prepare an English translation of the report (but not of any annexes) and will transmit such translation to those Offices.

4. REMINDER

The applicant must enter the national phase before each elected Office by performing certain acts (filing translations and paying national fees) within 30 months from the priority date (or later in some Offices) (Article 39(1)) (see also the reminder sent by the International Bureau with Form PCT/IB/301).

Where a translation of the international application must be furnished to an elected Office, that translation must contain a translation of any annexes to the international preliminary examination report. It is the applicant's responsibility to prepare and furnish such translation directly to each elected Office concerned.

For further details on the applicable time limits and requirements of the elected Offices, see Volume II of the PCT Applicant's Guide.

1. This international preliminary examination report has been prepared by this International Preliminary Examining Authority and is transmitted to the applicant according to Article 36.

2. This REPORT consists of a total of 9 sheets, including this cover sheet.

- ☒ This report is also accompanied by ANNEXES, i.e. sheets of the description, claims and/or drawings which have been amended and are the basis for this report and/or sheets containing rectifications made before this Authority (see Rule 70.16 and Section 607 of the Administrative Instructions under the PCT).

These annexes consist of a total of 15 sheets.

3. This report contains indications relating to the following items:

- I ☒ Basis of the report
- II ☐ Priority
- III ☒ Non-establishment of opinion with regard to novelty, inventive step and industrial applicability
- IV ☐ Lack of unity of invention
- V ☒ Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement
- VI ☐ Certain documents cited
- VII ☒ Certain defects in the international application
- VIII ☒ Certain observations on the international application

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT**

International application No. PCT/GB98/03810

I. Basis of the report

1. This report has been drawn on the basis of (*substitute sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to the report since they do not contain amendments.*):

Description, pages:

2,4,5,7-10,16	as originally filed	
1,3,6,11-15,17, 18	with telefax of	13/01/2000

Claims, No.:

4 (part),5-7,8 (part), 14-24	as originally filed	
1-3,4 (part),8 (part), 9-13	with telefax of	13/01/2000

Drawings, sheets:

1/7-4/7	as originally filed	
5/7-7/7	with telefax of	13/01/2000

2. The amendments have resulted in the cancellation of:

- ☐ the description, pages:
☐ the claims, Nos.:
☐ the drawings, sheets:

3. ☐ This report has been established as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed (Rule 70.2(c)):

4. Additional observations, if necessary:

see separate sheet

EXAMINATION REPORT**

International application No. PCT/GB98/03810

III. Non-establishment of opinion with regard to novelty, inventive step and industrial applicability

The questions whether the claimed invention appears to be novel, to involve an inventive step (to be non-obvious), or to be industrially applicable have not been examined in respect of:

☐ the entire international application.

☒ claims Nos. 23, 24.

because:

☐ the said international application, or the said claims Nos. relate to the following subject matter which does not require an international preliminary examination (*specify*):

☒ the description, claims or drawings (*indicate particular elements below*) or said claims Nos. 23, 24 are so unclear that no meaningful opinion could be formed (*specify*):

see separate sheet

☐ the claims, or said claims Nos. are so inadequately supported by the description that no meaningful opinion could be formed.

☐ no international search report has been established for the said claims Nos. .

V. Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement**1. Statement**

Novelty (N)	Yes:	Claims	1-22
	No:	Claims	none
Inventive step (IS)	Yes:	Claims	none

VIII. Certain observations on the international application

The following observations on the clarity of the claims, description, and drawings or on the question whether the claims are fully supported by the description, are made:

see separate sheet

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/GB98/03810

Re Item I**Basis of the report**

Claims 1 and 12 are based on the corresponding original claims 1 and 12, resp., and the description, page 2, lines 18-22.

Re Item III**Non-establishment of opinion with regard to novelty, inventive step and industrial applicability**

No opinion will be given for **claims 23 and 24** because they rely on references to the description and the drawings, contrary to the requirements of Rule 6.2(a) PCT. Moreover, they do not contain any technical feature, contrary to Rule 6.3(a) (see also PCT/GL/III-2.1.)

Re Item V**Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement****1. Reference is made to the following documents:**

D1: US-A-5 440 561 (WERRONEN ALTON P) 8 August 1995

D2: WO 97 44983 A (QUALCOMM INC) 27 November 1997

D3: US-A-5 267 261 (BLAKENEY II ROBERT D ET AL) 30 November 1993

D4: EP-B-0705524 (Eizenhöfer, Daimler-Benz Aerospace) 10 April 1996

The document D4 was not cited in the international search report.

2. Article 33(3) PCT

a) The document D1 is regarded as being the closest prior art to the subject-matter of **claim 1**, and discloses a method for establishing frame synchronization as necessary prior to the hand-off of a mobile unit from a serving base station to a target base station in a cellular TDMA communication system (see abstract, fig. 2 and the description column 3, line 57 - column 6, line 27).

b) The problem to be solved by the present invention may be regarded as

INTERNATIONAL PRELIMINARY

International application No. PCT/GB98/03810

EXAMINATION REPORT - SEPARATE SHEET

improving fast hand-off operation in a cellular communication system

c) The subject-matter of **claim 1** differs from the state of the art, as represented by D1, only in that:

the method includes mobile transmitted data detected at the first base station being used by the second base station to increase detection probability of the transmitted data by the second base station

d) The solution proposed in **claim 1** of the present application cannot be considered as involving an inventive step (Article 33(3) PCT) for the following reasons.

Document D1 already discloses that a serving base station, i.e. a "first" base station, in order to support hand-off of a mobile to a target base station, sends information (e.g. timing information) to a Mobile Telephone Switching Office. The target base station, i.e. a "second" base station, is informed by the MTSO and provided with information facilitating the hand-off procedure.

Without further qualification, the expression "detection probability" can be read to mean "probability that the data from the mobile station can be detected or recovered". Clearly the probability is increased if synchronisation is achieved.

e) Therefore **claim 1** does not involve an inventive step in the sense of Article 33(3) PCT.

f) The above objection regarding inventive step holds in an analogous way also for **claim 12**.

g) Dependent **claims 2-4, 6-11, 13-15, 17-22** do not contain any features which, in combination with the features of any claim to which they refer, meet the requirements of the PCT in respect of inventive step, the reasons being as follows:

i) the features of **claims 3, 4 and 7-9** are obvious or already disclosed by document D1 (see fig. 3, 310, for claim 3; see abstract, last sentence, for claim 4; claim 7 is implicitly disclosed because the first base station is the serving base station (fig. 2); see abstract (first sentence and calculation of

INTERNATIONAL PRELIMINARY

International application No. PCT/GB98/03810

EXAMINATION REPORT - SEPARATE SHEET

timing difference) for claim 8 and 9) and therefore not inventive

ii) the objections to the method claims 3, 4 and 7-9 hold in an analogous way also for the apparatus **claims 14, 15 and 18-20**

iii) **claims 10, 11, 21 and 22** are obvious because traffic data frames commonly are composed of predefined sequences (e.g. flags or control fields) and unknown information data

iv) **claims 2 and 13** merely describe a well known radio propagation problem of different receiving power levels at different locations. This problem would also be present if the data received by the first base station were not used by the second base station and therefore the claims are obvious

v) **claims 6 and 17** describe the well known technique of determining the direction of a moving mobile station which is already disclosed in D4 (cf. page 1, lines 8-28).

Re Item VII**Certain defects in the international application****1. Rule 6 PCT**

a) The features of the claims are not provided with reference signs placed in parentheses (Rule 6.2(b) PCT).

b) The independent **claims 1 and 12** are not in the two-part form in accordance with Rule 6.3(b) PCT, with those features known in combination from the prior art (document D1) being placed in a preamble (Rule 6.3(b)(i) PCT) and with the remaining features being included in a characterising part (Rule 6.3(b)(ii) PCT).

Nor has the applicant ensured that it is clear from the description which features of the subject-matter of the independent claims are known from document D1 (see the PCT Guidelines PCT/GL/III, 2.3 a).

2. Contrary to the requirements of Rule 5.1(a)(ii) PCT, the relevant background art

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/GB98/03810

disclosed in the document D1 is not mentioned in the description, nor is this document identified therein.

Re Item VIII**Certain observations on the international application****1. Article 6 PCT**

a) Claims 1 and 12 do not meet the requirements of Article 6 PCT in that the matter for which protection is sought is not clearly defined. The claims attempt to define the subject-matter in terms of the result to be achieved (namely, increasing the detection probability of the transmitted data by the second base station) which merely amounts to a statement of the underlying problem. The following technical features necessary for achieving this result are not defined (see pages 14-17, line 26):

- (1) the first base station descrambles the received data traffic with the delayed descrambling code and the descrambled data traffic is then integrated over a data symbol period T_s . Upon peak detection, the time delay and the distance to the mobile are stored (page 14, lines 10-19)
- (2) after successful estimation of the time delay the correct portion of the received data is selected and the information data is detected and stored (page 15, lines 14-20). Time delay and distance are sent to MSC and stored
- (3) the second base station tunes its receiver at the expected time of arrival of the data frame from the mobile. Then the second base station receives and stores the traffic data from the mobile. When a specified time has elapsed the second base station obtains (via network elements) and stores information data detected and stored by the first base station. The second base station then processes the stored information data and scrambles it in a similar manner as the mobile and stores it. This stored processed and scrambled information data is then used as a "data descrambling code" to descramble the received data traffic (page 17, lines 1-6)

Moreover, it seems that if those features would have been included in **claims 1 and 12**, these claims could have been regarded as involving an inventive step.

b) The passage "...the data is used to extend and increase the processing gain of

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/GB98/03810

the receiver in **claim 5**, page 20, lines 8-9, is not clear because a receiver has not been defined before in the previous claims.

c) All the features in the apparatus **claim 12** relate to a method of using the apparatus rather than clearly defining the apparatus in terms of its technical features. The intended limitations are therefore not clear from this claim, contrary to the requirements of Article 6 PCT.

1

APPARATUS AND METHOD FOR DETECTION OF SIGNALS

- 5 The present invention relates to method and apparatus for detection of signals, particularly in a cellular communications network requiring location information and fast hand-off operation.
- 10 In cellular communications networks such as IS95, a mobile terminal in communication with a base station enjoys closed and open loop transmit power control. This effectively means that the mobile terminal transmission powers are optimised such that, at the
- 15 serving base station, the received signal levels are at a substantially constant minimum level for adequate detection, set by the desired quality of the communications link. If the mobile terminal is in communication with more than one serving base station,
- 20 e.g. during soft hand-off period, the combined power or the strongest received signal (or a combination of the above two techniques) is kept to a substantially constant minimum level of adequate detection set by the desired quality of the communications link. The power
- 25 control mechanism ensures that the multiple access interference, caused by a mobile terminal, within or outside the cell covered by the serving base station is kept to a minimum.
- 30 Although power control is desirable and even essential

AMENDED SHEET

being used by the second base station to increase detection probability of the transmitted data by the second base station.

- 5 Preferably, the signal received by the first base station is of sufficient quality to enable detection of the data transmitted by the signal. More preferably the detected data is used by the second base station(s), where the mobile terminal transmissions are
- 10 not received with sufficient power for adequate detection, to enable detection of the data by the second base station(s).

- The detection process of the second base station(s) may
- 15 be based on serial correlation, matched filter correlation, maximum likelihood sequence estimation, joint-detection or multiuser detection or any combination of these.

- 20 The detection process at the second base station(s) preferably includes detection of the presence of the data detected at the first base station(s).

- The detection process at the second base station(s)
- 25 preferably includes detection and calculation of the received time delay caused by signal propagation due to the distance of the mobile terminal from the respective base station.

- 30 The detection process at the second base station(s) may

mobile terminal wherein at a given time at least one of the base stations is a serving base station and the mobile terminal is served by the serving base station; the serving base station is capable of receiving and
5 detecting data transmitted to it by the mobile terminal and the detected data is usable by the serving base station and/or at least one other base station to increase detection probability of the transmitted data.

10 An embodiment of the present invention will now be described by way of example only referring to the accompanying drawings in which:

Figure 1 is a schematic drawing of a general embodiment
15 of the invention.

Figure 2 is a schematic drawing showing the components of part of a first base station of an embodiment of the invention.

20

Figure 3 is a schematic drawing showing the components of part of a second base station of an embodiment of the invention.

25 Figure 4 is a graphical representation of a data frame structure typically transmitted by the first and second base stations.

Figure 5 is a schematic drawing showing the components
30 of a scrambler for scrambling and spreading the data

The first, the second and the third base stations 104, 108, 107 are all capable of transmitting a sequence of 20 msec data frames having a data frame structure 400 (shown in Figure 4). The data frame 400 has a
5 structure comprising information data portions 436, 438, 440, 442, 444, 446, 448, 450, 452, 454, 456, 458, 460, 462, 464, 466, 468. The frame structure 400 also comprises 16 power control data portions, 404, 406, 408, 410, 412, 414, 416, 418, 420, 422, 424, 426, 428,
10 430, 432, 434.

The data frame 400 is scrambled and spread by scrambler code 500. Spreading is, to broaden the signalling bandwidth of the data frame 400. The scrambler
15 includes several codes 504, 506, 508, 510, known to all network components, ie. base stations 104, 108 and 107 and mobile terminal 120.

Referring to Fig. 5. The data is scrambled and spread
20 by LC code 504, at multiplier 512. The data is further scrambled by Walsh code 506 at multiplier 514. The resulting scrambled data is then, once scrambled by I code 510 for in phase transmission at multiplier 516, and once by Q code 508 for quadrature phase
25 transmission at multiplier 518. The resulting scrambling and spreading code is referred to, for this example, as scrambling code 502.

The scrambling code 502 is used for calculation of
30 various parameters, for example channel estimation,

frame synchronisation and coherent detection of data. The mobile terminal 120 operations are synchronised to the scrambling code 502.

- 5 The mobile terminal 120 is capable of transmitting a sequence of 20 msec data frames having a data structure 600. The data frame 600 consists mostly of information data portion.
- 10 The data frame 600 is scrambled and spread by scrambler 700. Spreading is, to broaden the signalling bandwidth of the data frame 600. The scrambler 700, includes several codes 704, 708, 706 known to all network components, i.e. base stations 104, 107 and 108 and
- 15 mobile terminal 120.

Referring to Fig. 7. The data is scrambled and spread by LC code 704 at multiplier 710. The resulting scrambled and spread data is then once scrambled by I

20 code 708 for in phase transmission, at multiplier 712, and once by Q code 706 for quadrature phase transmission at multiplier 714. The resulting scrambling and spreading code is referred to, for this example, as scrambling code 702.

25

The operation of the above cellular system 100 will now be described below.

A call is established according to any known method in

30 the art. The first base station 104 being in

communication with the mobile terminal 120 and a first traffic channel (tch) is allocated. Data frames having the structure of the first data frame structure 400 are transmitted from first base station 104 and received by mobile terminal 120. Data frames having the structure of the second data frame structure 600 are transmitted from mobile terminal 120 and received by first base station 104. The first base station 104 by means of power control data 404, 406, 408, 410, 412, 414, 416, 418, 420, 422, 424, 426, 428, 430, 432, 434 controls the transmit power of the mobile terminal 120 according to techniques well known in the art. The data frames 600 received by the first base station antenna 202 are of only sufficient power for correct detection of propagation time delay and information data by the first base station 104. By information data, it is meant the unknown information data which is present in the data frames 400 and data frames 600.

Hence the mobile terminal 120 transmit power, is of sufficient magnitude to overcome the propagation losses to the first base station 104 only. The second and the third base Stations 106, 107 not in communication with the mobile terminal 120 may suffer excessive propagation losses such that they are unable to receive the transmitted data frames 600 by the mobile terminal 120, with sufficient power for reliable and successful detection of time delay and information data.

A method of detection of information data 828 and time

- delay 824 for the first base station 104 is outlined in Figure 8 and is as follows. The synthesiser 210 of the first base station 104 is tuned to receive a data frame 600 at the expected time of arrival, transmitted from the mobile terminal 120 (step 802). As traffic data frame 600 is received, in the specified time frame, by the first base station 104, the traffic data is stored (step 806).
- 10 The first base station 104 then determines (step 808) whether sufficient time has elapsed to receive the entire data frame 600. Considering the longest propagation time delay expected, due to distance between the first base station 104 and the mobile terminal 120. If sufficient time has not elapsed, the first base station 104 continues to receive and store the traffic data (step 806). When the specified time has elapsed, the first base station 104 initialises the expected time delay (T) to zero (step 810).
- 20 The descrambling code which is similar to scrambling code 702 at the time of transmission of the data frame 600 by the mobile terminal 120 (which is known in the art as code synchronised) is then delayed by the specified time delay T (step 812). The first base station 104 descrambles the received data traffic with the delayed descrambling code 702 (step 814). The descrambled data traffic is then summed (integrated) over a data symbol period T_s (step 818).

- If no substantial peak is detected by the first base station 104, the expected time delay T is increased (by a set amount) (step 820) and the steps 812, 814, 816, 818 and 820 are repeated until a substantial peak is detected. After the detection of a substantial peak, the first base station 104, calculates and stores the time delay and further calculates the distance from the mobile terminal 120 (step 822).
- 10 In the presence of multipath propagation, several peaks may be detected, where one or more peaks can be used for data detection.
- 15 After the successful estimation of the time delay between the first base station 104 and the mobile terminal 120, the correct portion of the received traffic data is selected at the data frame portion 600, transmitted by the mobile terminal 120 (step 826), the information data contained in the data frame 600 is
- 20 then detected and stored (step 828).
- The time delay and the distance between the first base station 104 and the mobile terminal 120 are sent to MSC 114, and stored.
- 25 A method of detection of time delay for the second base station 108 is outlined in Figure 9 and is as follows.
- The synthesiser 310 of the second base station 108 is
- 30 tuned at the expected time of arrival of data frame 600

The second base station 108 then proceeds to initialise the expected time delay T to zero (step 916). The "data descrambling code" is then delayed by the specified delay T (step 918). The second base station 5 108 descrambles the received data traffic with the "data descrambling code" (step 920). The descrambled data traffic is then summed (integrated) over sufficient long time, T_i to ensure reliable and successful detection of mobile terminal 120 transmitted 10 data frame 600 (step 922). T_i is long enough to provide sufficient noise bandwidth reduction, thus providing sufficient signal-to-noise ratio gain, known in the art as "processing gain", to account for all possible excess propagation losses experienced by the 15 second base station 108, compared to that experienced by the first base station 104.

The second base station 108 then determines whether a substantial peak is detected as a result of the 20 summation (step 928). If no peak is detected by the second base station 108, the expected time delay T is increased (step 924), and the step 918, 920, 922, 926 and 924 are repeated until a substantial peak is detected. After the detection of an acceptable peak, 25 the second base station 108 calculates and stores the time delay and further calculates the distance the mobile terminal 120 is from the second base station 108 (step 928).

30 The third base station 107 operates a method of

detection of time delay substantially identical to that explained above for the second base station 108.

5 The time delay and distance between the second base station 108 and the mobile terminal 120 are sent to MSC 114 and stored. The time delay and distance between the third base station 107 and the mobile terminal 120 are sent to MSC 114 and stored. The MSC 114 uses, by a method known in the art as triangulation, the stored
10 data on the distance of the mobile terminal 120 from the first and second and the third base stations 104, 108, 107 the known coordinates of the first, the second and the third base stations 104, 108, 107 to estimate the coordinates of the mobile terminal 120.

15 The remaining components of a cellular communication system base station are well known in the art and need not be described in detail herein.

20 The above embodiments of the present invention have been described by way of example only and various alternative features or modifications from what has been described can be made within the scope of the invention, as will be readily apparent to persons
25 skilled in the art.

CLAIMS

1. A method of detection of signals in a communication network including a mobile terminal, at least one first base station serving the mobile terminal and at least one second base station wherein the method includes mobile transmitted data detected at the first base station being used by the second base station to increase detection probability of the transmitted data by the second base station.
2. A method according to claim 1 wherein the signal received by the first base station is of sufficient quality to enable detection of the data transmitted by the signal and the detected data is used by the second base station, where the mobile terminal transmissions are not received with sufficient power for adequate detection, to enable detection of the data by the second base station.
3. A method according to claim 1 or claim 2 wherein the detection process at the second base station(s) includes detection and calculation of the received time delay caused by signal propagation due to the distance of the mobile terminal from the respective base station.
4. A method according to any one of claims 1 - 3 wherein the detection process at the second base

station to a second base station.

9. A method according to any one of claims 1 - 8 in which the detection process at the second base station(s) includes detection of the presence of the data detected at the first base station(s).

10. A method according to any of claims 1 - 9 in which the data transmitted by the mobile terminal is unknown information data.

11. A method according to any of claims 1 - 9 in which the data transmitted by the mobile terminal is a predefined sequence.

12. A system for detection of signals in a communications network including a plurality of base stations and a mobile terminal wherein at a given time at least one of the base stations is a first serving base station and the mobile terminal is served by the first serving base station; the first serving base station is capable of receiving and detecting data transmitted to it by the mobile terminal and the detected data is usable by the first serving base station and/or at least one second base station to increase detection probability of the transmitted data.

13. A system according to claim 12 wherein the signal received by the first base station is of sufficient quality to enable detection of the data transmitted by

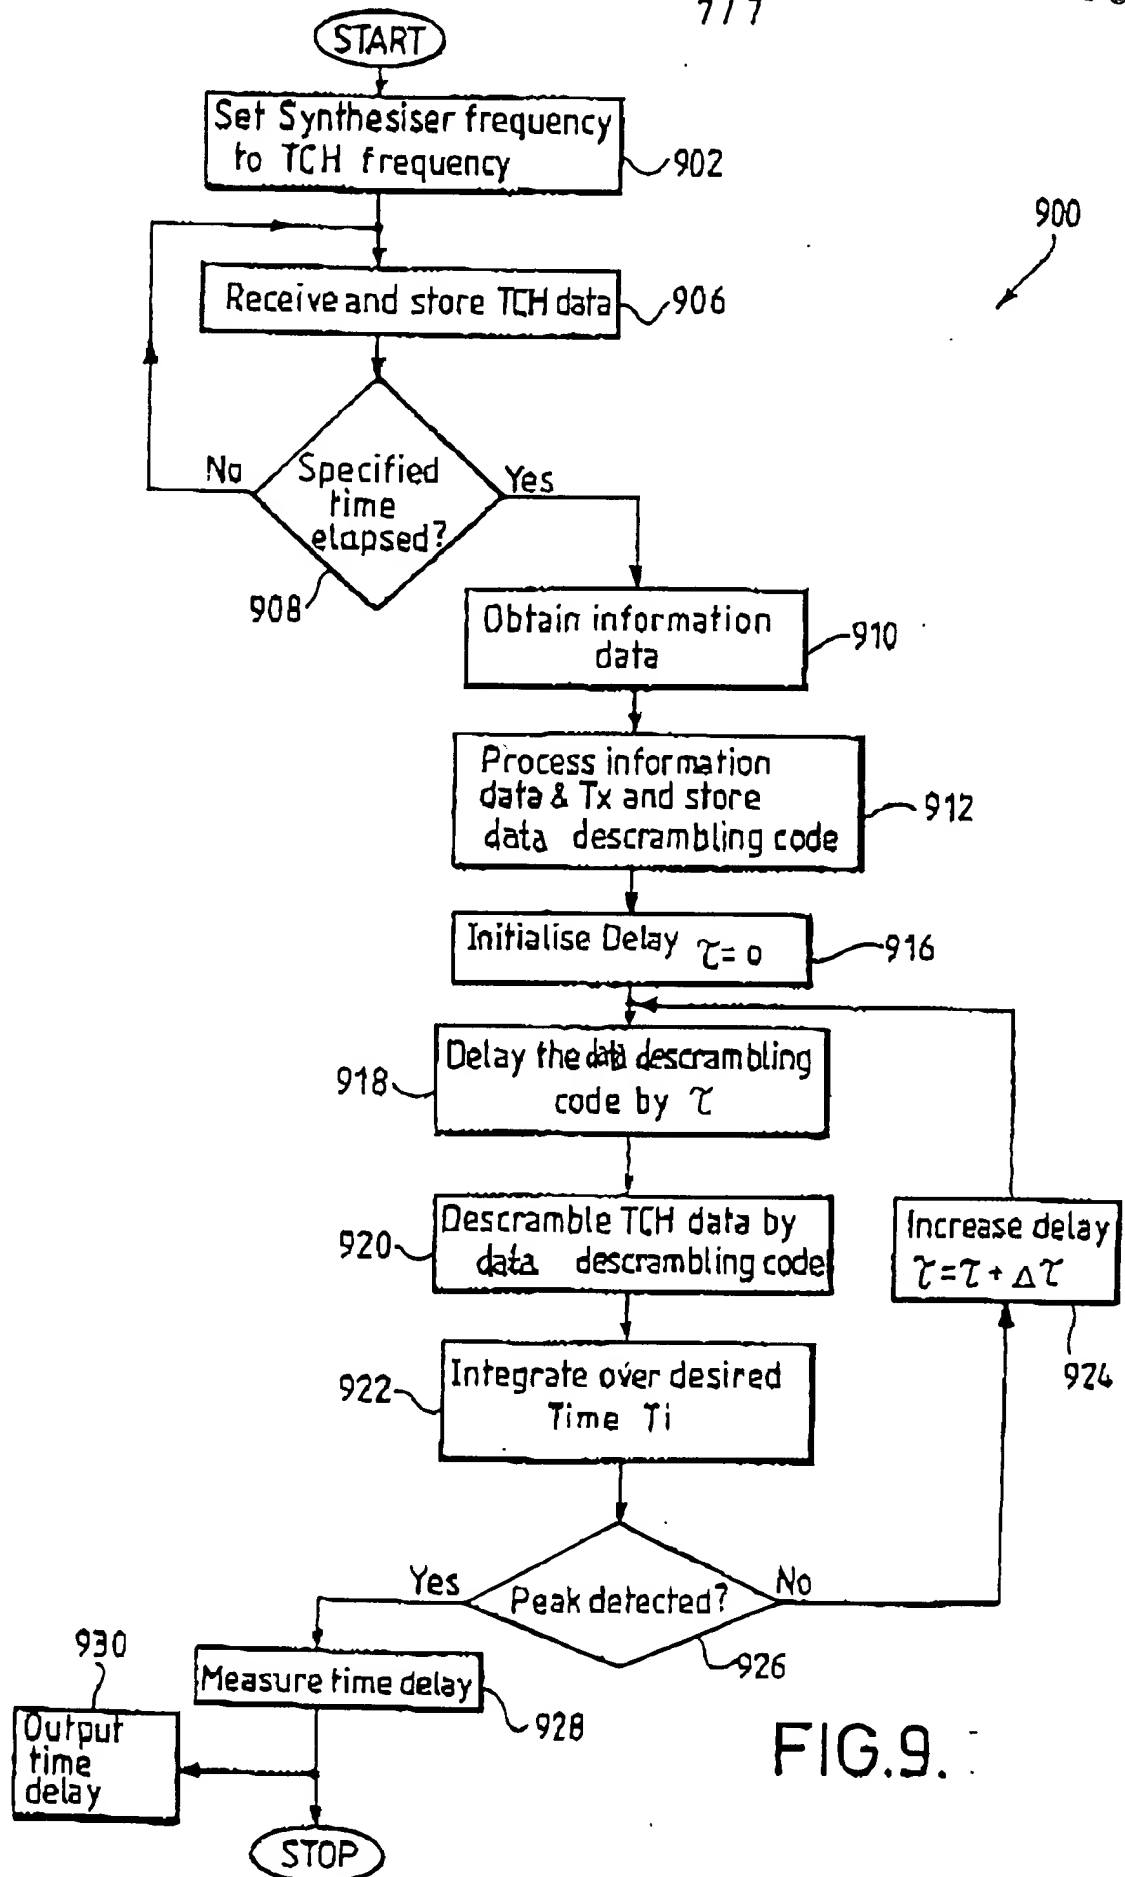

FIG. 9.

PATENT COOPERATION TREATY

PCT

NOTIFICATION OF ELECTION

(PCT Rule 61.2)

From the INTERNATIONAL BUREAU

To:

Assistant Commissioner for Patents
United States Patent and Trademark
Office
Box PCT
Washington, D.C. 20231
ÉTATS-UNIS D'AMÉRIQUE

in its capacity as elected Office

Date of mailing (day/month/year) 17 August 1999 (17.08.99)	
International application No. PCT/GB98/03810	Applicant's or agent's file reference NJH/MP5742739
International filing date (day/month/year) 17 December 1998 (17.12.98)	Priority date (day/month/year) 19 December 1997 (19.12.97)
Applicant SFANDIARI, Hossein	

1. The designated Office is hereby notified of its election made:

☒ in the demand filed with the International Preliminary Examining Authority on:

13 July 1999 (13.07.99)

☐ in a notice effecting later election filed with the International Bureau on:

2. The election
- ☒
- was

☐ was not

made before the expiration of 19 months from the priority date or, where Rule 32 applies, within the time limit under Rule 32.2(b).

The International Bureau of WIPO

PCT

INTERNATIONAL SEARCH REPORT

(PCT Article 18 and Rules 43 and 44)

Applicant's or agent's file reference NJH/MP5742739	FOR FURTHER ACTION see Notification of Transmittal of International Search Report (Form PCT/ISA/220) as well as, where applicable, item 5 below.	
International application No. PCT/GB 98/ 03810	International filing date (day/month/year) 17/12/1998	(Earliest) Priority Date (day/month/year) 19/12/1997
Applicant ADVANCED COMMUNICATIONS CONSULTANCYet al.		

This International Search Report has been prepared by this International Searching Authority and is transmitted to the applicant according to Article 18. A copy is being transmitted to the International Bureau.

This International Search Report consists of a total of 3 sheets.

It is also accompanied by a copy of each prior art document cited in this report.

1. Basis of the report

- a. With regard to the **language**, the international search was carried out on the basis of the international application in the language in which it was filed, unless otherwise indicated under this item.

the international search was carried out on the basis of a translation of the international application furnished to this Authority (Rule 23.1(b)).

- b. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the international search was carried out on the basis of the sequence listing :

contained in the international application in written form.

filed together with the international application in computer readable form.

furnished subsequently to this Authority in written form.

furnished subsequently to this Authority in computer readable form.

the statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.

the statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished

2. ☐ **Certain claims were found unsearchable** (See Box I).

3. ☐ **Unity of invention is lacking** (see Box II).

4. With regard to the **title**,

the text is approved as submitted by the applicant.

the text has been established by this Authority to read as follows:

APPARATUS AND METHOD FOR SIGNAL DETECTION BY BASE STATION IN A MOBILE COMMUNICATION SYSTEM

5. With regard to the **abstract**,

the text is approved as submitted by the applicant.

the text has been established, according to Rule 38.2(b), by this Authority as it appears in Box III. The applicant may, within one month from the date of mailing of this international search report, submit comments to this Authority.

6. The figure of the **drawings** to be published with the abstract is Figure No.

as suggested by the applicant.

because the applicant failed to suggest a figure.

because this figure better characterizes the invention.

1

None of the figures.

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT**

International application No. PCT/GB98/03810

I. Basis of the report

1. This report has been drawn on the basis of (*substitute sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to the report since they do not contain amendments.*):

Description, pages:

2,4,5,7-10,16	as originally filed	
1,3,6,11-15,17, 18	with telefax of	13/01/2000

Claims, No.:

4 (part),5-7,8 (part), 14-24	as originally filed	
1-3,4 (part),8 (part), 9-13	with telefax of	13/01/2000

Drawings, sheets:

1/7-4/7	as originally filed	
5/7-7/7	with telefax of	13/01/2000

2. The amendments have resulted in the cancellation of:

- ☐ the description, pages:
☐ the claims, Nos.:
☐ the drawings, sheets:

3. ☐ This report has been established as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed (Rule 70.2(c)):

4. Additional observations, if necessary:

see separate sheet

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No. PCT/GB98/03810

III. Non-establishment of opinion with regard to novelty, inventive step and industrial applicability

The questions whether the claimed invention appears to be novel, to involve an inventive step (to be non-obvious), or to be industrially applicable have not been examined in respect of:

- ☐ the entire international application.
- ☒ claims Nos. 23, 24.

because:

- ☐ the said international application, or the said claims Nos. relate to the following subject matter which does not require an international preliminary examination (*specify*):
- ☒ the description, claims or drawings (*indicate particular elements below*) or said claims Nos. 23, 24 are so unclear that no meaningful opinion could be formed (*specify*):

see separate sheet
- ☐ the claims, or said claims Nos. are so inadequately supported by the description that no meaningful opinion could be formed.
- ☐ no international search report has been established for the said claims Nos. .

V. Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

1. Statement

VII. Certain defects in the international application

The following defects in the form or contents of the international application have been noted:

see separate sheet

VIII. Certain observations on the international application

The following observations on the clarity of the claims, description, and drawings or on the question whether the claims are fully supported by the description, are made:

see separate sheet

Re Item I

Basis of the report

Claims 1 and 12 are based on the corresponding original claims 1 and 12, resp., and the description, page 2, lines 18-22.

Re Item III

Non-establishment of opinion with regard to novelty, inventive step and industrial applicability

No opinion will be given for **claims 23 and 24** because they rely on references to the description and the drawings, contrary to the requirements of Rule 6.2(a) PCT. Moreover, they do not contain any technical feature, contrary to Rule 6.3(a) (see also PCT/GL/III-2.1.)

Re Item V

Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

1. Reference is made to the following documents:

- D1: US-A-5 440 561 (WERRONEN ALTON P) 8 August 1995
- D2: WO 97 44983 A (QUALCOMM INC) 27 November 1997
- D3: US-A-5 267 261 (BLAKENEY II ROBERT D ET AL) 30 November 1993
- D4: EP-B-0705524 (Eizenhöfer, Daimler-Benz Aerospace) 10 April 1996

The document D4 was not cited in the international search report.

2. Article 33(3) PCT

a) The document D1 is regarded as being the closest prior art to the subject-matter of **claim 1**, and discloses a method for establishing frame synchronization as necessary prior to the hand-off of a mobile unit from a serving base station to a target base station in a cellular TDMA communication system (see abstract, fig. 2 and the description column 3, line 57 - column 6, line 27).

b) The problem to be solved by the present invention may be regarded as

improving fast hand-off operation in a cellular communication system

c) The subject-matter of **claim 1** differs from the state of the art, as represented by D1, only in that:

the method includes mobile transmitted data detected at the first base station being used by the second base station to increase detection probability of the transmitted data by the second base station

d) The solution proposed in **claim 1** of the present application cannot be considered as involving an inventive step (Article 33(3) PCT) for the following reasons.

Document D1 already discloses that a serving base station, i.e. a "first" base station, in order to support hand-off of a mobile to a target base station, sends information (e.g. timing information) to a Mobile Telephone Switching Office. The target base station, i.e. a "second" base station, is informed by the MTSO and provided with information facilitating the hand-off procedure.

Without further qualification, the expression "detection probability" can be read to mean "probability that the data from the mobile station can be detected or recovered". Clearly the probability is increased if synchronisation is achieved.

e) Therefore **claim 1** does not involve an inventive step in the sense of Article 33(3) PCT.

f) The above objection regarding inventive step holds in an analogous way also for **claim 12**.

g) Dependent **claims 2-4, 6-11, 13-15, 17-22** do not contain any features which, in combination with the features of any claim to which they refer, meet the requirements of the PCT in respect of inventive step, the reasons being as follows:

i) the features of **claims 3, 4 and 7-9** are obvious or already disclosed by document D1 (see fig. 3, 310, for claim 3; see abstract, last sentence, for claim 4; claim 7 is implicitly disclosed because the first base station is the serving base station (fig. 2); see abstract (first sentence and calculation of

timing difference) for claim 8 and 9) and therefore not inventive

ii) the objections to the method claims 3, 4 and 7-9 hold in an analogous way also for the apparatus **claims 14, 15 and 18-20**

iii) **claims 10, 11, 21 and 22** are obvious because traffic data frames commonly are composed of predefined sequences (e.g. flags or control fields) and unknown information data

iv) **claims 2 and 13** merely describe a well known radio propagation problem of different receiving power levels at different locations. This problem would also be present if the data received by the first base station were not used by the second base station and therefore the claims are obvious

v) **claims 6 and 17** describe the well known technique of determining the direction of a moving mobile station which is already disclosed in D4 (cf. page 1, lines 8-28).

Re Item VII

Certain defects in the international application

1. Rule 6 PCT

a) The features of the claims are not provided with reference signs placed in parentheses (Rule 6.2(b) PCT).

b) The independent **claims 1 and 12** are not in the two-part form in accordance with Rule 6.3(b) PCT, with those features known in combination from the prior art (document D1) being placed in a preamble (Rule 6.3(b)(i) PCT) and with the remaining features being included in a characterising part (Rule 6.3(b)(ii) PCT).

Nor has the applicant ensured that it is clear from the description which features of the subject-matter of the independent claims are known from document D1 (see the PCT Guidelines PCT/GL/III, 2.3 a).

2. Contrary to the requirements of Rule 5.1(a)(ii) PCT, the relevant background art

disclosed in the document D1 is not mentioned in the description, nor is this document identified therein.

Re Item VIII

Certain observations on the international application

1. Article 6 PCT

a) Claims 1 and 12 do not meet the requirements of Article 6 PCT in that the matter for which protection is sought is not clearly defined. The claims attempt to define the subject-matter in terms of the result to be achieved (namely, increasing the detection probability of the transmitted data by the second base station) which merely amounts to a statement of the underlying problem. The following technical features necessary for achieving this result are not defined (see pages 14-17, line 26):

- (1) the first base station descrambles the received data traffic with the delayed descrambling code and the descrambled data traffic is then integrated over a data symbol period T_s . Upon peak detection, the time delay and the distance to the mobile are stored (page 14, lines 10-19)
- (2) after successful estimation of the time delay the correct portion of the received data is selected and the information data is detected and stored (page 15, lines 14-20). Time delay and distance are sent to MSC and stored
- (3) the second base station tunes its receiver at the expected time of arrival of the data frame from the mobile. Then the second base station receives and stores the traffic data from the mobile. When a specified time has elapsed the second base station obtains (via network elements) and stores information data detected and stored by the first base station. The second base station then processes the stored information data and scrambles it in a similar manner as the mobile and stores it. This stored processed and scrambled information data is then used as a "data descrambling code" to descramble the received data traffic (page 17, lines 1-6)

Moreover, it seems that if those features would have been included in **claims 1 and 12**, these claims could have been regarded as involving an inventive step.

b) The passage "...the data is used to extend and increase the processing gain of

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/GB98/03810

the receiver" in **claim 5**, page 20, lines 8-9, is not clear because a receiver has not been defined before in the previous claims.

c) All the features in the apparatus **claim 12** relate to a method of using the apparatus rather than clearly defining the apparatus in terms of its technical features. The intended limitations are therefore not clear from this claim, contrary to the requirements of Article 6 PCT.

(54) Title: APPARATUS AND METHOD FOR SIGNAL DETECTION BY BASE STATION IN A MOBILE COMMUNICATION SYSTEM

(57) Abstract

The present invention provides a method of detection of signals in a communication network (100) (e.g. cellular) including a mobile terminal (120), at least one first base station (104) serving the mobile terminal (120) and at least one second base station (108) wherein the method includes mobile transmitted data detected at the first base station being used by the second base station to increase detection of the transmitted data by the second base station.

APPARATUS AND METHOD FOR SIGNAL DETECTION BY BASE STATION IN A MOBILE COMMUNICATION SYSTEM

- 5 The present invention relates to method and apparatus for detection of signals, particularly in a cellular communications network requiring location information and fast hand-off operation.
- 10 In cellular communications networks such as IS95, a mobile terminal in communication with a base station enjoys closed and open loop transmit power control. This effectively means that the mobile terminal transmission powers are optimised such that, at the
- 15 servicing base station, the received signal levels are at a substantially constant minimum level for adequate detection, set by the desired quality of the communications link. If the mobile terminal is in communication with more than one serving base station,
- 20 e.g. during soft hand-off period, the combined power or the strongest received signal (or a combination of the above two techniques) is kept to a substantially constant minimum level of adequate detection set by the desired quality of the communications link. The power
- 25 control mechanism ensures that the multiple access interference, caused by a mobile terminal, within or outside the cell covered by the serving base station is kept to a minimum.
- 30 Although power control is desirable and even essential

in systems such as direct sequence spread spectrum code division multiple access (DS-CDMA), it reduces the ability of base stations, not serving a given mobile terminal, to receive and detect the mobile terminal transmissions adequately and reliably. The reliable
5 detection of mobile terminal transmissions by base stations other than the serving base stations is desirable for services such as "location" and for "hand off" operations. It is therefore desirable to increase
10 the detection ability of non-serving base stations without any increase in mobile terminal transmission power, so that information such as propagation time delay (i.e. distance) and mobile terminal signal power strength are available with a received signal well
15 below the minimum required level for adequate information data detection.

The present invention sets out preferably to increase the detection ability of a mobile terminal transmitted
20 signal by a cellular communications network, or signal transmitted by a first and second base stations and detected by a mobile terminal.

According, a first aspect of the present invention
25 provides a method of detection of signals in a communication network (e.g. cellular) including a mobile terminal, at least one first base station serving the mobile terminal and at least one second base station wherein the method includes mobile
30 transmitted data detected at the first base station

being used by the second base station to increase detection of the transmitted data by the second base station.

5 Preferably, the signal received by the first base station is of sufficient quality to enable detection of the data transmitted by the signal. More preferably the detected data is used by the second base station(s), where the mobile terminal transmissions are
10 not received with sufficient power for adequate detection, to enable detection of the data by the second base station(s).

The detection process of the second base station(s) may
15 be based on serial correlation, matched filter correlation, maximum likelihood sequence estimation, joint-detection or multiuser detection or any combination of these.

20 The detection process at the second base station(s) preferably includes detection of the presence of the data detected at the first base station(s).

The detection process at the second base station(s)
25 preferably includes detection and calculation of the received time delay caused by signal propagation due to the distance of the mobile terminal from the respective base station.

30 The detection process at the second base station(s) may

additionally or alternatively include detection of the received signal power of the mobile terminal transmission signal by the second base station(s).

5 Preferably the mobile terminal is served by the first base station over a communications channel. More preferably, the communications channel is a traffic channel, an access channel or a control channel, which can be operated in a packet or circuit switched mode.

10

The cellular communications network is preferably a direct sequence spread spectrum code division multiple access (DS-CDMA) system and the data is preferably used to extend and increase the processing gain of the
15 receiver by enabling longer integration times at the base stations. More preferably the network system is a GSM or GSM derivative system.

The location of the mobile terminal may be determined
20 from the network system by e.g. using the received time delay at each respective base station, using the direction of the mobile terminal from each respective base station, or a combination of received time delay and/or direction of the mobile terminal from a first
25 base station(s) and received time delay and/or direction of the mobile terminal from a second base station(s).

The process of determining the location of the mobile
30 terminal using three or more fixed base stations of

known position is known in the art as triangulation or trilatituration.

Preferably, the data received by at least the first
5 base station is capable of identifying the mobile terminal in the network system.

The measured signal power of the mobile terminal may be used for hand-off preparation from a first base station
10 to a second base station.

Preferably the data transmitted by the mobile terminal is unknown information data.

15 Alternatively, or additionally, preferably the data transmitted by the mobile terminal is a predefined sequence.

The data received by the first base station may be used
20 by that station as well as or instead of the second base station to improve detection of the transmitted data by the mobile station.

Preferably, Spatial filtering is used at the second
25 base station(s) to reduce the effect of the propagation channel(s) on the received signal.

A second aspect of the invention provides a system for detection of signals in a communications network (e.g.
30 cellular) including a plurality of base stations and a

mobile terminal wherein at a given time at least one of the base stations is a serving base station and the mobile terminal is served by the serving base station; the serving base station is capable of receiving and
5 detecting data transmitted to it by the mobile terminal and the detected data is usable by the serving base station and/or at least one other base station to increase detection of the transmitted data.

10 An embodiment of the present invention will now be described by way of example only referring to the accompanying drawings in which:

Figure 1 is a schematic drawing of a general embodiment
15 of the invention.

Figure 2 is a schematic drawing showing the components of part of a first base station of an embodiment of the invention.

20 Figure 3 is a schematic drawing showing the components of part of a second base station of an embodiment of the invention.

25 Figure 4 is a graphical representation of a data frame structure typically transmitted by the first and second base stations.

Figure 5 is a schematic drawing showing the components
30 of a scrambler for scrambling and spreading the data

frame shown in Figure 4.

Figure 6 is a graphical representation of a data frame structure typically transmitted by the mobile terminal.

5

Figure 7 is a schematic drawing showing the components of a scrambler for scrambling and spreading the data frame shown in Figure 6.

10 Figure 8 is a flow diagram showing the operative steps of the part of the first base station shown schematically in Figure 2.

15 Figure 9 is a flow diagram showing the operative steps of the part of the second base station shown schematically in Figure 3.

A cellular system 100 (Fig. 1) installed in a geographical area, for example, a city centre 102 comprises a first base station 104 having a first associated coverage area 106 and a second base station 108 having a second associated coverage area 110, and a third base station 107 and associated coverage area 111.

25

The first, the second and the third base stations 104, 108, 107 are independently connected to a base station controller (BSC) 112, the BSC 112 being connected to a mobile switching centre (MSC) 114. The MSC 114 is in communication with a fixed terminal 116 via a public

30

switched telecommunication network (PSTN) 118.

An example of the first, the second and the third base stations 104, 108, 107 are units of Supercell (trade mark) base stations manufactured by Motorola. The Supercell base stations have appropriate hardware and/or software modifications so as to be capable of functioning with time delay estimation units 220, 320. A mobile terminal 120 is located within the first coverage area 106 and the second coverage area 110. However, it is not essential for the mobile terminal 120 to be located within the second coverage area 110. The mobile terminal 120 can be located in the vicinity of the second and third coverage areas 110, 111.

As example of the mobile terminal 120, is a Qualcomm QCP/820 model cellular telephone.

Referring to Fig. 2, the first base station 104 comprises a receiver chain 200. The receiver chain 200 has an antenna 202 coupled to a low noise amplifier 204. The low noise amplifier 204 being coupled to a bandpass filter 206. The bandpass filter 206 is coupled to a mixer 208. The mixer 208 being coupled to a lowpass filter 212 and a synthesiser unit 210. The lowpass filter 212 is coupled to an analogue to digital converter (ADC) 214 which is coupled to a digital signal processor (DSP) 218 via a buffer 216.

The buffer 216 is also coupled to delay estimation unit

220. The delay estimation unit 220 is also coupled to the DSP 218. Within the delay estimation unit 220, the buffer output is coupled to a multiplier 222. The multiplier 222 is coupled to an integrator 224 and a variable delay unit 226. The integrator unit 224 is coupled to a peak detector 230, and is to integrate received data over a transmitted symbol period T_s , which is set to an initial value of zero at the beginning of each correlation operation i.e. starting at the beginning of each received data symbol. The output of the peak detector 230 is coupled to processor 232. The variable delay unit 226 is coupled to both processor 232 and the code unit 228. Finally, the clock 234 is coupled to processor unit 232. The clock 234 is also coupled to code unit 228.

The receiver is operating with both in phase and quadrature phase components present (i.e. complex data).

The above described receiver chain 200 is shown for exemplary purposes only and can also form a part of a transceiver circuit (not shown).

Referring to Fig. 3., the second and third base stations 108, 107 each include a receiver chain 300. The receiver chain 300 has an antenna 302 coupled to a low noise amplifier 304. The low noise amplifier 304 being coupled to a bandpass filter 306. The bandpass filter 306 is coupled to a mixer 308. The mixer 308

being coupled to a lowpass filter 312 and a synthesiser unit 310. The lowpass filter 312 is coupled to an analogue to digital converter (ADC) 314 which is coupled to a buffer 316. The buffer unit is coupled to
5 a delay estimation unit 320. Within the delay estimation unit 320, the buffer output is coupled to a multiplier 322.

The multiplier 322 is coupled to an integrator 324 and
10 a variable delay unit 326. The integrator unit 324 is also coupled to a peak detector 330. The integrator 324, having been set to an initial value of zero at the beginning of each correlation operation i.e. at the beginning of a received data block, is to integrate
15 received data for a desired period T_i . The output of the peak detector 330 is coupled to a processor 332. The variable delay unit 326 is coupled to multiplier 329 and is also coupled to processor 332. A clock 334 is coupled to processor 332. The multiplier 329 is
20 coupled to both a DSP unit 319 and a code unit 328. The DSP unit is coupled to information data unit 318. The clock 334 is also coupled to the code unit 328.

The receiver chain is operating with both in phase and
25 quadrature phase components present (i.e. complex data).

The above described receiver chain 300 is shown for exemplary purposes only and can also form a part of a
30 transceiver circuit (not shown).

The first, the second and the third base stations 104, 108, 107 are all capable of transmitting a sequence of 20 msec data frames having a data frame structure 400 (shown in Figure 4). The data frame 400 has a
5 structure comprising information data portions 436, 438, 440, 442, 444, 446, 448, 450, 452, 454, 456, 458, 460, 462, 464, 466, 468. The frame structure 400 also comprises 16 power control data portions, 404, 406, 408, 410, 412, 414, 416, 418, 420, 422, 424, 426, 428,
10 430, 432, 434.

The data frame 400 is scrambled and spread by scrambler code 500. Spreading is, to broaden the signalling bandwidth of the data frame 400. The scrambler
15 includes several codes 504, 506, 508, 510, known to all network components, ie. base stations 104, 108 and 107 and mobile terminal 120.

Referring to Fig. 5. The data is scrambled and spread
20 by LC code 504, at multiplier 512. The data is further scrambled by Walsh code 506 at multiplier 514. The resulting scrambled data is then, once scrambled by I code 510 for in phase transmission at multiplier 516, and once by Q code 508 for quadrature phase
25 transmission at multiplier 518. The resulting scrambled and spread codes are referred to, for this example, as scrambling code 502.

The scrambling code 502 is used for calculation of
30 various parameters, for example channel estimation,

frame synchronisation and coherent detection of data.
The mobile terminal 120 operations are synchronised to
the scrambling code 502.

- 5 The mobile terminal 120 is capable of transmitting a
sequence of 20 msec data frames having a data structure
600. The data frame 600 consists mostly of information
data portion.
- 10 The data frame 600 is scrambled and spread by scrambler
700. Spreading is, to broaden the signalling bandwidth
of the data frame 600. The scrambler 700, includes
several codes 704, 712, 706 known to all network
components, i.e. base stations 104 and 108 and mobile
15 terminal 120.

- Referring to Fig. 7. The data is scrambled and spread
by LC code 704 at multiplier 710. The resulting
scrambled and spread data is then once scrambled by I.
20 code 708 for in phase transmission, at multiplier 712,
and once by Q code 706 for quadrature phase
transmission at multiplier 714. The resulting
scrambled and spread codes are referred to, for this
example, as scrambling code 702.

- 25 The operation of the above cellular system 100 will now
be described below.

- A call is established according to any known method in
30 the art. The first base station 104 being in

communication with the mobile terminal 120 and a first traffic channel (tch) is allocated. Data frames having the structure of the first data frame structure 400 are transmitted from first base station 104 and received by mobile terminal 120. Data frames having the structure of the second data frame structure 600 are transmitted from mobile terminal 120 and received by first base station 104. The first base station 104 by means of power control data 404, 406, 408, 410, 412, 414, 416, 418, 420, 422, 424, 426, 428, 430, 432, 434 controls the transmit power of the mobile terminal 120 according to techniques well known technique in the art. The data frames 600 received by the first base station antenna 202 are of only sufficient power for correct detection of propagation time delay and information data by the first base station 104. By information data, it is meant the unknown information data which is present in the data frames 400 and data frames 600.

Hence the mobile terminal 120 transmit power, is of sufficient magnitude to overcome the propagation losses to the first base station 104 only. The second and the third base Stations 108, 107 not in communication within the mobile terminal 120 may suffer excessive propagation losses such that they are unable to receive the transmitted data frames 600 by the mobile terminal 120, with sufficient power for reliable and successful detection of time delay and information data.

A method of detection of information data 828 and time

delay 829 for the first base station 104 is outlined in Figure 8 and is as follows. The synthesiser 210 of the first base station 104 is tuned to receive a data frame 600 at the expected time of arrival, transmitted from the mobile terminal 120 (step 802). As traffic data frame 600 is received, in the specified time frame, by the first base station 104, the traffic data is stored (step 806).

10 The first base station 104 then determines (step 808) whether sufficient time has elapsed to receive the entire data frame 600. Considering the longest propagation time delay expected, due to distance between the first base station 104 and the mobile

15 terminal 120. If sufficient time has not elapsed, the first base station 104 continues to receive and store the traffic data (step 806). When the specified time has elapsed, the first base station 104 initialises the expected time delay (T) to zero (step 810).

20 The descrambling code which is similar to scrambling code 702 at the time of transmission of the data frame 600 by the mobile terminal 120 (which is known in the art as code synchronised) is then delayed by the

25 specified time delay T (step 812). The first base station 104 descrambles the received data traffic with the delayed descrambling code 702 (step 814). The descrambled data traffic is then summed (integrated) over a data symbol period T_s (step 818).

If no substantial peak is detected by the first base station 104, the expected time delay T is increased (by a set amount) (step 820) and the steps 812, 814, 816, 818 and 820 are repeated until a substantial peak is
5 detected. After the detection of a substantial peak, the first base station 104, calculates and stores the time delay and further calculates the distance from the mobile terminal 120 (step 822).

10 In the presence of multipath propagation, several peaks may be detected, where one or more peaks can be used for data detection.

After the successful estimation of the time delay
15 between the first base station 104 and the mobile terminal 120, the correct portion of the received traffic data is selected at the data frame portion 600, transmitted by the mobile terminal 120 (step 826), the information data contained in the data frame 600 is
20 then detected and stored (step 428).

The time delay and the distance between the first base station 104 and the mobile terminal 120 are sent to MSC 114, and stored.

25 A method of detection of time delay for the second base station 108 is outlined in Figure 9 and is as follows.

The synthesiser 310 of the second base station 108 is
30 tuned at the expected time of arrival of data frame 600

16

to receive the data frame 600, transmitted from the mobile terminal 120 (step 902). As traffic data is received, in the specified time, by the second base station 108, the traffic data is stored (step 906).

5

The second base station then determines (step 908) whether sufficient time has elapsed to receive the entire data frame 600, allowing for the longest expected propagation time delay caused by the distance between the second base station 108 and the mobile terminal 120. If sufficient time has not elapsed, the second base station 108 continues to receive and store the traffic data (step 906). When the specified time has elapsed, the second base station 108 obtains and stores information data 318 detected and stored at step 828, by the first base station 104, via network elements, e.g. BSC 112 (step 910).

10

15

The second base station 108 then processes 319 the stored information data 318 and scrambles it with scrambling code 702, 328 in a similar manner to the processing and scrambling performed by the mobile terminal 120 on the original information data, prior to transmission of data frame 600 and stores it (step 912). After step 912, the stored processed and scrambled information data, referred to now as "data descrambling code" is substantially similar in envelope and phase to the transmitted data frame 600 by the mobile terminal 120.

20

25

30

The second base station 108 then proceeds to initialise the expected time delay T to zero (step 916). The "data descrambling code" is then delayed by the specified delay T (step 918). The second base station 5 108 descrambles the received data traffic with the "data descrambling code" (step 920). The descrambled data traffic is then summed (integrated) over sufficient long time, T_i to ensure reliable and successful detection of mobile terminal 120 transmitted 10 data frame 600 (step 922). T_i is long enough to provide enough processing gain to account for all possible excess propagation losses experienced by the second base station 108, compared to that experienced by the first base station 104.

15

The second base station 108 then determines whether a substantial peak is detected as a result of the summation (step 928). If no peak is detected by the second base station 108, the expected time delay T is 20 increased (step 924), and the step 918, 920, 922, 926 and 924 are repeated until a substantial peak is detected. After the detection of an acceptable peak, the second base station 108 calculates and stores the time delay and further calculates the distance the 25 mobile terminal 120 is from the second base station 108 (step 928).

The third base station 107 operates a method of detection of time delay substantially identical to that 30 explained above for the second base station 108.

The time delay and distance between the second base station 108 and the mobile terminal 120 are sent to MSC 114 and stored. The time delay and distance between the third base station 107 and the mobile terminal 120 are sent to MSC 114 and stored. The MSC 114 uses, by a method known in the art as triangulation, the stored data on the distance of the mobile terminal 120 from the first and second and the third base stations 104, 108, 107 the known coordinates of the first, the second and the third base stations 104, 108, 107 to estimate the coordinates of the mobile terminal 120.

The remaining components of a cellular communication system base station are well known in the art and need not be described in detail herein.

The above embodiments of the present invention have been described by way of example only and various alternative features or modifications from what has been described can be made within the scope of the invention, as will be readily apparent to persons skilled in the art.

CLAIMS

1. A method of detection of signals in a communication network including a mobile terminal, at least one first base station serving the mobile terminal and at least one second base station wherein the method includes mobile transmitted data detected at the first base station being used by the second base station to increase detection of the transmitted data by the second base station.

2. A method according to claim 1 wherein the signal received by the first base station is of sufficient quality to enable detection of the data transmitted by the signal and the detected data is used by the second base station, where the mobile terminal transmissions are not received with sufficient power for adequate detection, to enable detection of the data by the second base station.

3. A method according to claim 1 or claim 2 wherein the detection process at the second base station(s) includes detection and calculation of the received time delay caused by signal propagation due to the distance of the mobile terminal from the respective base station.

4. A method according to any one of claims 1 - 3 wherein the detection process at the second base

station(s) includes detection of the received signal power of the mobile terminal transmission signal by the second base station.

5 5. A method according to any of claims 1 - 4 wherein the communications network is a cellular communications direct sequence spread spectrum code division multiple access (DS-CDMA) system and the data is used to extend and increase the processing gain of the receiver by
10 enabling longer integration times at the base stations.

6. A method according to any one of claims 1 - 5 in which the location of the mobile terminal is determined from the network system by any one of some or all
15 of: (a) using the received time delay at each respective base station, (b) using the direction of the mobile terminal from each respective base station and, (c) a combination of received time delay and/or direction of the mobile terminal from a first base station(s) and
20 received time delay and/or direction of the mobile terminal from a second base station(s).

7. A method according to any one of claims 1 - 6 in which the data received by at least the first base
25 station is capable of identifying the mobile terminal in the network system.

8. A method according to any one of claims 1 - 7 in which the measured signal power of the mobile terminal
30 is used for hand-off preparation from a first base

station to a second base station.

9. A method according to any one of claims 1 - 8 in which the detection process at the second base
5 station(s) includes detection of the presence of the data detected at the first base station(s).

10. A method according to any of claims 1 - 9 in which the data transmitted by the mobile terminal is unknown
10 information data.

11. A method according to any of claims 1 - 9 in which the data transmitted by the mobile terminal is a predefined sequence.
15

12. A system for detection of signals in a communications network including a plurality of base stations and a mobile terminal wherein at a given time at least one of the base stations is a first serving
20 base station and the mobile terminal is served by the first serving base station; the first serving base station is capable of receiving and detecting data transmitted to it by the mobile terminal and the detected data is usable by the first serving base
25 station and/or at least one second base station to increase detection of the transmitted data.

13. A system according to claim 12 wherein the signal received by the first base station is of sufficient
30 quality to enable detection of the data transmitted by

the signal and the second base station, where the mobile terminal transmissions are not received with sufficient power for adequate detection, includes means for using the detected data to enable detection of the data by the second base station.

14. A system according to claim 12 or 13 wherein the second base station includes means for detection and calculation of the received time delay caused by signal propagation due to the distance of the mobile terminal from the respective base station.

15. A system according to any one of claims 12 - 14 wherein the second base station includes means for detection of the received signal power of the mobile terminal transmission signal by the second base station.

16. A system according to any one of claims 12 - 15 wherein the communications network is a cellular communication direct sequence spread spectrum code division multiple access (DS-CDMA) system and it includes means for using the data to extend and increase the processing gain of the receiver by enabling longer integration times at the base stations.

17 A system according to any one of claims 12- 16 including means for the location of the mobile terminal to be determined from the network system by any one, some or all of : (a) using the received time delay at

each respective base station, (b) using the direction of the mobile terminal from each respective base station, and (c) a combination of received time delay and/or direction of the mobile terminal from a first
5 base station(s) and received time delay and/or direction of the mobile terminal from a second base station(s).

18. A system according to claims 12- 17 including
10 means for using the data received by at least the first base station to identify the mobile terminal in the network system.

19. A system according to claims 12- 18 including
15 means for using the measured signal power of the mobile terminal for hand-off preparation from a first base station to a second base station.

20. A system according to any one of claims 12 - 19 in
20 which the second base station(s) includes means for detection of the presence of the data detected at the first base station(s).

21. A method according to any of claims 12 - 20 in
25 which the data transmitted by the mobile terminal is unknown information data.

22. A method according to any of claims 12 - 20 in
30 which the data transmitted by the mobile terminal is a predefined sequence.

24

23. A method of detection of signals subsequently as any one embodiment herein described or referenced to the accompanying drawings.

5 24. A system for detection of signals subsequently as any one embodiment herein described or referenced to the accompanying drawings.
